[14/08/2019] [Aquatic Plant Management]

Why should we manage lake vegetation?

Mary de Winton

Rotorua Te Arawa Lakes have vegetation that includes the bad, alien weeds,

and the good, indigenous plant species

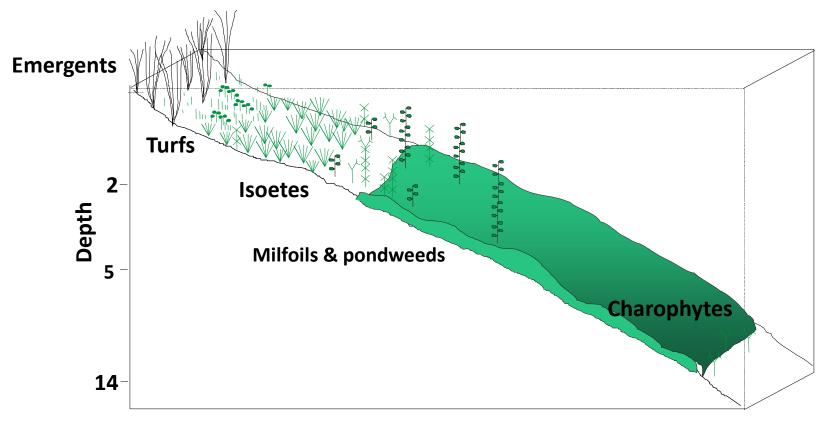

Why should vegetation be managed?

- Reduce recreational, cultural & utility impacts
- Prevent further weed spread (biosecurity)
- Improve ecological condition?

Introduction to native lake plants

• Five 'life-forms' by depth

Emergents (reeds & rushes)

- Require some shelter
- Soft sediments

Turf plants (amphibious)

- Tolerate moderate wave action
- Soft to sandy sediments
- Like regular water level fluctuation
- Often species grow intermingled

Isoetes (quillwort)

- Must be submerged
- Tolerate strong wave action
- Soft, sandy, even rocky sediments
- Decreased abundance since 1980s

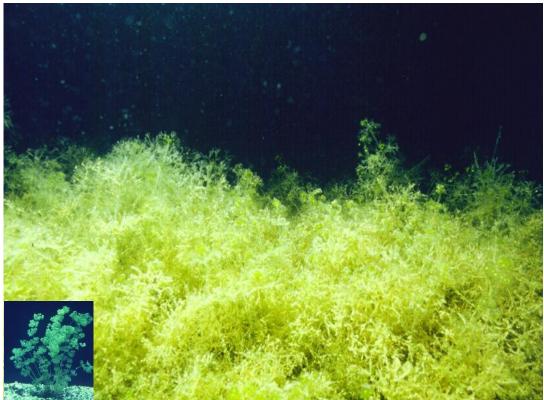

Milfoils & Pondweeds

- Submerged, but flower at surface
- Open beds, co-exist with other plants
- Rarely deeper than 5 m, might be limited by pressure

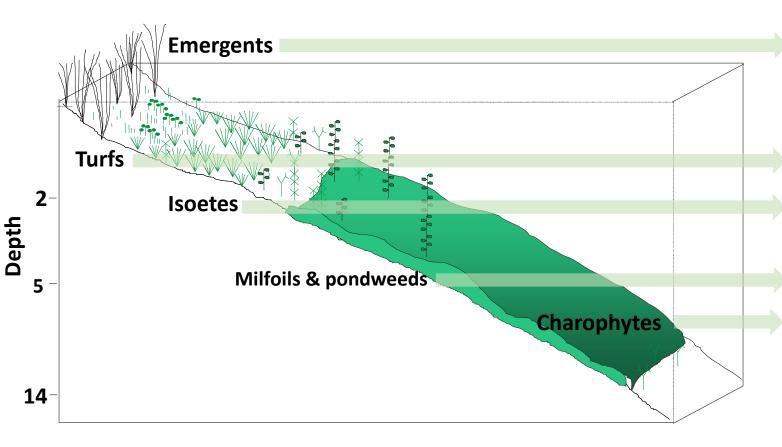

Charophytes

- Macro-algae, look like higher plants
- Found shallows to deep
- Depth only limited by light
- Can form carpets in deeper water

Roles of native plants

Filter dissolved inorganic N from groundwater, buffer wave action on shores

Potential high endemic diversity, 'geotextile' role

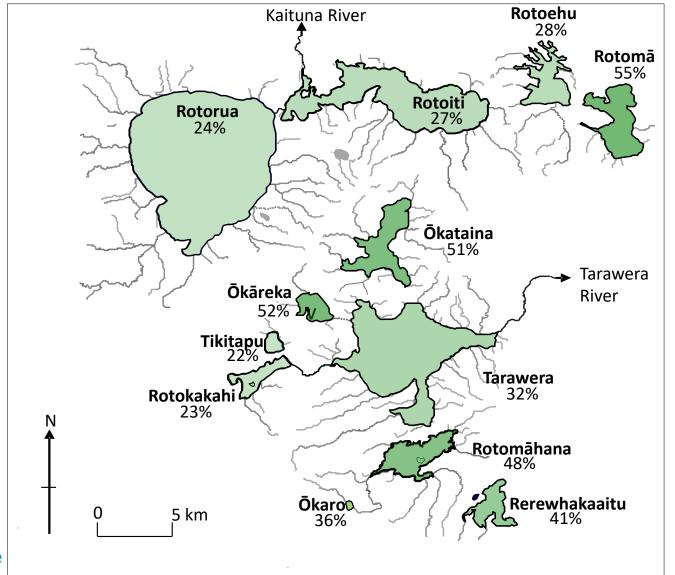

Indicate good water quality, carbon harvesting, strong influence on sediment processes

Large surface area, waterfowl food

Water 'grooming', extend vegetated zone in clear lakes, vegetation resilience via seed bank role

Native plant status

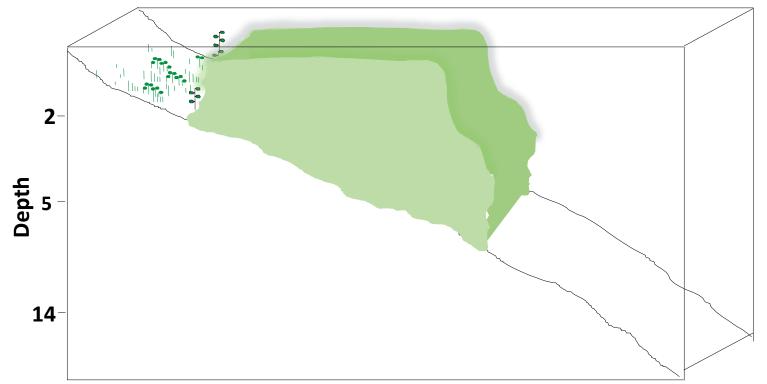

Darker green = higher native vegetation development using biomonitoring tool LakeSPI (Native Condition Index)

Introduction to invasive weeds

- Four major weeds invade mid depth range of lakes
- Form tall, closed canopy, weed beds. No seed vegetative fragments

Hornwort

- No roots
- Invades wide range of nutrient conditions
- Can grow to >10 m depth
- Beds 3-4 m tall
- Illegal to propagate, sell, distribute

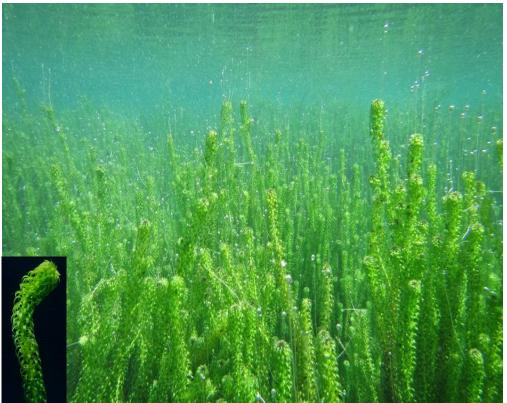

Egeria

- Less dominant under low nutrients
- Can have boom-bust growth
- Grows up to 8-10 m depth
- Beds 2.5-3 m tall
- Illegal to propagate, sell, distribute

Lagarosiphon

- Widespread in the lakes, hornwort & Egeria replace it
- Can grow to 6 m depth
- Beds 3.3 m tall
- Illegal to propagate, sell, distribute

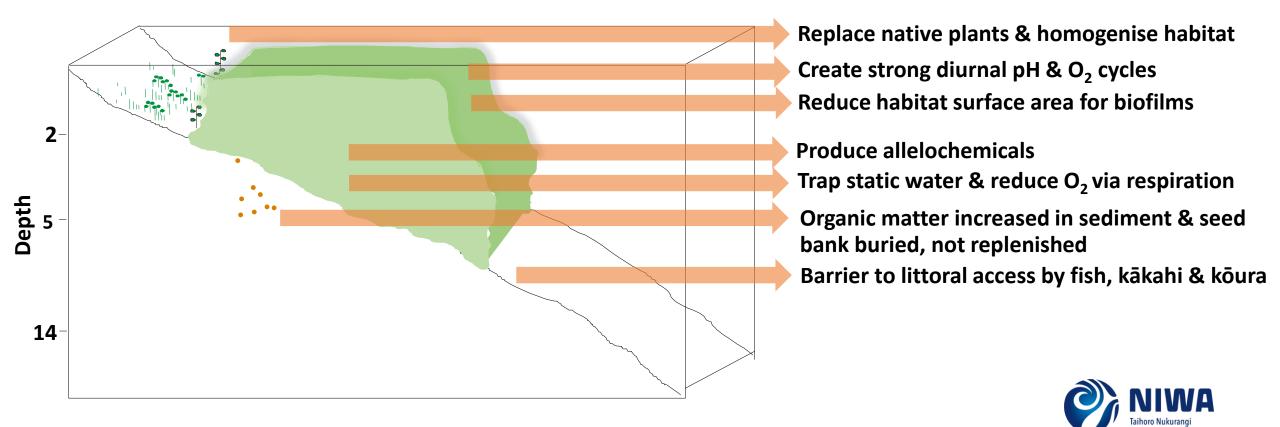

Elodea (Canadian pondweed)

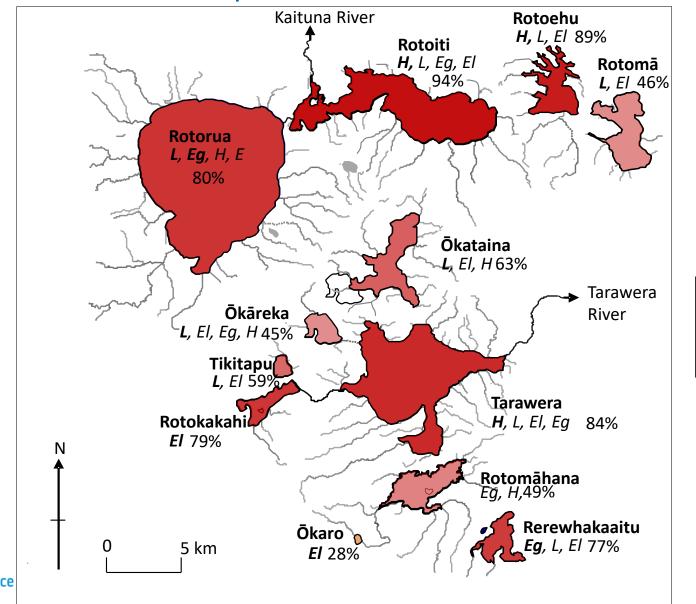

- Pioneer weed
- Can co-exist with natives- low nutrients
- Replaced by other invasive species
- Grows to 10 m depth
- Up to 3 m tall
- Is legal in trade as 'oxygen weed'

Impacts of invasive weeds

Invasive plant status

Darker red = higher weed dominance using biomonitoring tool LakeSPI (Invasive Impact Index)

Hornwort (H) Egeria (Eg) Lagarosiphon (L) Elodea (El)

History of weed invasion

	1950	1960	1970	1980	1990	2000	2010	2020	Current status	
Rotomā			i —					÷-	*	
Tikitapu									∞ †	
Rotomāhana						_			*	
Ōkataina		_				-			*	Species Elodea
Rerewhakaaitu									∞ † *	Lagarosiphon Egeria
Ōkāreka									×++++	Hornwort
Rotokakahi									*	Status * Dominant
Ōkaro									+	+ Common
Tarawera									* *	∞ Uncommon ‡ Contained
Rotorua									× * *	
Rotoiti									* * *	
Rotoehu						<u> </u>			*	

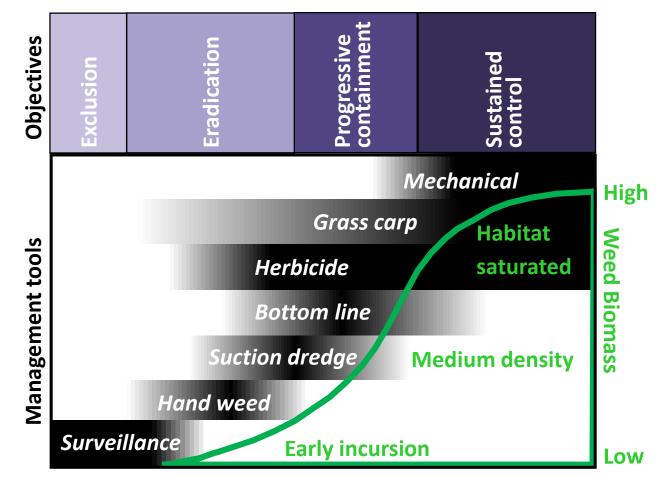

Weed Management

• Starts with protecting lakes, exclusion of weed, everyone's responsibility

Weed control tools

Hand weeding

- Used in conjunction with diver surveillance
- Only for scattered plants
- Need to remove all green material

Suction dredging

- Requires skilled operator & specialised gear
- Slow spatial progress, especially for dense weed
- Duration dependent on recolonisation
- Recolonisation fast where untreated adjacent areas

Hessian bottom lining

- Laid by divers
- Shades out weed (fine weave)
- Not for tall weed, large areas
- Not for exposed areas, uneven bottom, risk of propeller foul
- Allows native plants to grow through
- Breaks down by 18-24 months

Grass carp

- Must be contained
- Mob stocked & graze all plants
- Are long lived & difficult to catch
- But, can eradicate weed over time

Mechanical

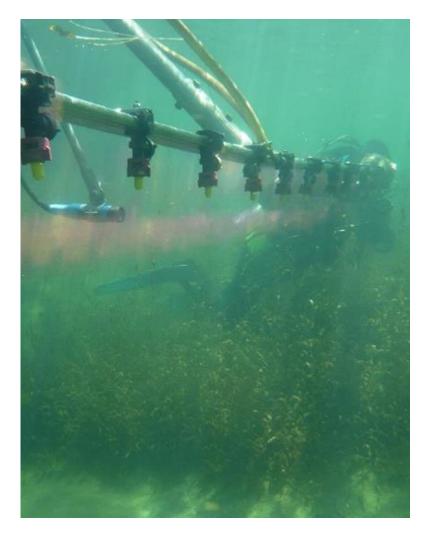

- Mows weed to 2m depth
- Can remove 50 ton per day
- Regrowth rapid, short duration control (2-3 months), can outstrip shoreline progress
- Impacts on some animals (bugs/fish)
- Not for very dense weed
- Noise

Herbicide

- Two herbicides for aquatic use (diquat, endothall)
- Reduces biomass, 'biostatic'
- Effective where contact time achieved, diquat for clean plants & water
- Little/no effect on native plants
- Achieves control at scale & within a short timeframe

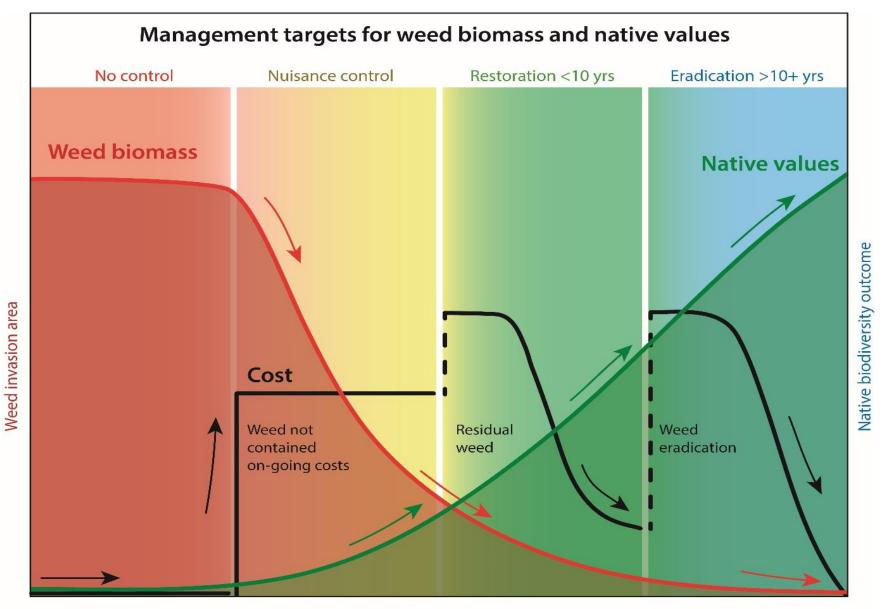

Manage aquatic weed further than nuisance control?

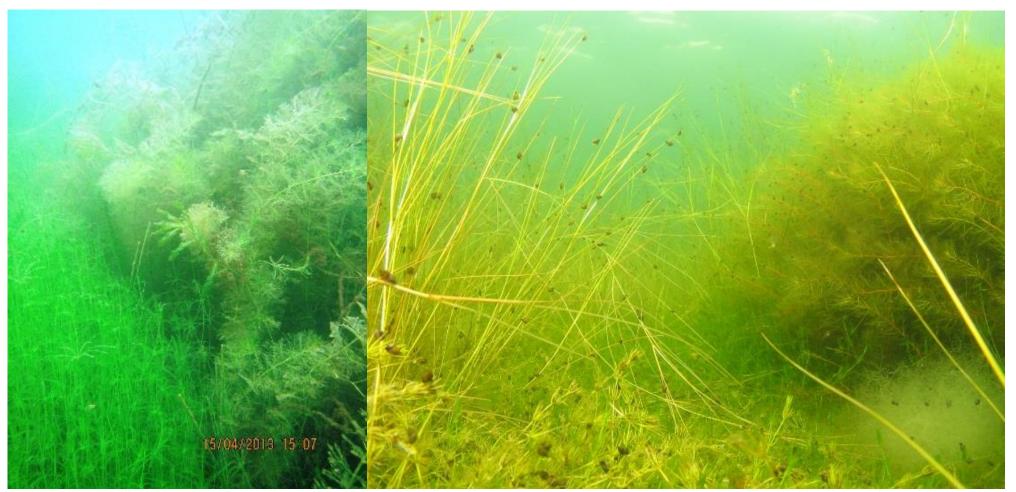

Changing management targets requires new actions with associated costs Target - Nuisance control Control cost high Surveillance cost low

Target - Restoration Control cost initially higher Surveillance cost moderate Target - Weed eradication and/or an increase in native biodiversity Minimal control cost Surveillance cost high & on-going

Biodiversity gains from aquatic weed control works?
